

Email Address Generator

Write a C++ program that generates an email address for a person using the following rule:

The email address will include the first six letters of the person's last name, followed by the underscore character, followed by the first letter of their first name. All characters should be lowercase.

Examples:

```
John Smith = smith_j@glebe.ca  
Sally Johnson = johnso_s@glebe.ca
```

Your program should prompt the user for their first name and last name and then display the email address.

All error checking should be included (ie. if they leave an input blank).
